

AMENDMENTS TO THE CLAIMS:

This listing of claims will replace all prior versions and listings of claims in the application:

1. (Currently amended) Elevator emergency stop device for an elevator cage guided on a guide rail, comprising:

a wedge-shaped element movable relative to the elevator cage to effect that ~~effects~~ an emergency stop of said elevator cage by frictional force by means of a contact face of a sliding part thereof being pressed against said guide rail,

wherein said wedge-shaped element comprises a fixed part and a movable part, the movable part being movable relative to the fixed part in a direction having a component parallel to said guide rail, such that ~~mechanism whereby~~ a dimension of said wedge-shaped element in the direction perpendicular to said contact face is changed in accordance with braking force to maintain the braking force at substantially constant level.

2. (Previously presented) Elevator emergency stop device for an elevator cage guided on a guide rail, comprising:

a wedge-shaped element that effects an emergency stop of said elevator cage by frictional force by means of a contact face of a sliding part thereof being pressed against said guide rail,

wherein said wedge-shaped element comprises:

a mechanism whereby a dimension of said wedge-shaped element in the direction perpendicular to said contact face is changed in accordance with braking force to maintain the braking force at a substantially constant level, the mechanism comprising

a fixed part having an outside inclined face part of said wedge-shaped element; and

a wedge-shaped moveable part having said sliding part;

said moveable part being moveable along an inside inclined face part of said fixed part and an upper part thereof being engaged with said fixed part by means of a resilient element.

3. (Original) Elevator emergency stop device according to claim 2, wherein in said wedge-shaped element said fixed part and said resilient element, and said resilient element and said moveable part are engaged by means of respective sliding elements between said resilient element and said moveable element and between said resilient element and said fixed element.

4. (Original) Elevator emergency stop device according to claim 2 or 3, wherein in said resilient element a relationship between a load and a flexure is such that said flexure is small or zero up to a prescribed load and above said prescribed load said relationship between said load and said flexure is a practically proportional relationship.

5. (Currently amended) Elevator emergency ~~Emergency~~ stop device according to claim 4,
wherein said resilient element comprises a piston in which is sealed gas that is given an initial pressure.
6. (New) Elevator emergency stop device according to claim 1, comprising a resilient element disposed between the fixed part and the movable part.
7. (New) Elevator emergency stop device according to claim 6, further comprising sliding elements disposed between said resilient element and said moveable part and disposed between said resilient element and said fixed part.
8. (New) Elevator emergency stop device according to claim 7, wherein said resilient element is configured to establish a relationship between a load and a flexure such that said flexure of said resilient element is small or zero up to a prescribed load, and flexure of said resilient element increases generally proportional to said load for loads above the prescribed load.
9. (New) Elevator emergency stop device according to claim 8, wherein said resilient element comprises a piston in which is a pressured gas.
10. (New) Elevator emergency stop device of claim 1, wherein the movable part is movable relative to the fixed part in an oblique direction relative to the guide rail.

11. (New) An elevator emergency stop device for an elevator cage guided on a guide rail, comprising:

a wedge-shaped element moveable relative to the elevator cage the wedge shaped element including

a fixed part; and

a movable part having a contact face configured to contact the guide rail and restrict movement of the elevator cage by frictional force, the movable part being movable relative to the fixed part; and

a resilient member disposed between the fixed part and the movable part and being configured to influence movement of the moveable part in a direction having a component substantially parallel to the guide rail.
